

MLRF Lecture 03

J. Chazalon, LRE/EPITA, 2025

Homography estimation

Geometric validation

Lecture 03 part 04

So we want to recover H from keypoint matches

Recover the parameters of a perspective transform

From our matched points we want to estimate H that maps from x to x'

$$xH = x'$$

How many degrees of freedom?

>> 8 (**not 9** because $h_{22} = 1$ **OR** $\|H\| = \sum h_{ij}^2 = 1$)

$$\begin{bmatrix} \tilde{x}' \\ \tilde{y}' \\ \tilde{w}' \end{bmatrix} = \begin{bmatrix} h_{00} & h_{01} & h_{02} \\ h_{10} & h_{11} & h_{12} \\ h_{20} & h_{21} & h_{22} \end{bmatrix} \begin{bmatrix} \tilde{x} \\ \tilde{y} \\ \tilde{w} \end{bmatrix}$$

How many knowns do we get with one match $mH = n$?

>> 2

$$n_x = (h_{00} * m_x + h_{01} * m_y + h_{02} * m_w) / (h_{20} * m_x + h_{21} * m_y + h_{22} * m_w)$$
$$n_y = (h_{10} * m_x + h_{11} * m_y + h_{12} * m_w) / (h_{20} * m_x + h_{21} * m_y + h_{22} * m_w)$$

How many correspondences are needed?

Depends on the type of transform:

- How many for translation?
- For rotation?
- ...
- For general projective transform?

Reminded: we have 2 knowns for each match

How many correspondences are needed?

Transformation	Matrix	# DoF	Min. # of independent matches required
translation	$\begin{bmatrix} \mathbf{I} & & \mathbf{t} \end{bmatrix}_{2 \times 3}$	2	1
rigid (Euclidean)	$\begin{bmatrix} \mathbf{R} & & \mathbf{t} \end{bmatrix}_{2 \times 3}$	3	2
similarity	$\begin{bmatrix} s\mathbf{R} & & \mathbf{t} \end{bmatrix}_{2 \times 3}$	4	2
affine	$\begin{bmatrix} \mathbf{A} \end{bmatrix}_{2 \times 3}$	6	3
projective	$\begin{bmatrix} \tilde{\mathbf{H}} \end{bmatrix}_{3 \times 3}$	8	4

Enforcing 8 DOF

Approach 1: set $h_{22} = 1$

$$x' = \frac{h_{00}x + h_{01}y + h_{02}}{h_{20}x + h_{21}y + 1}$$

$$y' = \frac{h_{10}x + h_{11}y + h_{12}}{h_{20}x + h_{21}y + 1}$$

Approach 2: Impose unit vector constraint

$$x' = \frac{h_{00}x + h_{01}y + h_{02}}{h_{20}x + h_{21}y + h_{22}}$$

$$y' = \frac{h_{10}x + h_{11}y + h_{12}}{h_{20}x + h_{21}y + h_{22}}$$

subject to the constraint

$$h_{00}^2 + h_{01}^2 + h_{02}^2 + \dots + h_{22}^2 = 1$$

Build an equation system to solve

Assuming $h_{22} = 1$ here:

$$x' = \frac{h_{00}x + h_{01}y + h_{02}}{h_{20}x + h_{21}y + 1}$$

Multiplying through by denominator:

$$(h_{20}x + h_{21}y + 1)x' = h_{00}x + h_{01}y + h_{02}$$

Rearrange:

$$h_{00}x + h_{01}y + h_{02} - h_{20}xx' + h_{21}yx' = x'$$

Same for y:

$$h_{10}x + h_{11}y + h_{12} - h_{20}xy' + h_{21}yy' = y'$$

Linear system with $h_{22} = 1$

unknowns

$$\begin{array}{c} \mathbf{M} \end{array}
 \begin{bmatrix}
 x_0 & y_0 & 1 & 0 & 0 & 0 & -x_0 x'_0 & -y_0 x'_0 \\
 0 & 0 & 0 & x_0 & y_0 & 1 & -x_0 y'_0 & -y_0 y'_0 \\
 x_1 & y_1 & 1 & 0 & 0 & 0 & -x_1 x'_1 & -y_1 x'_1 \\
 0 & 0 & 0 & x_1 & y_1 & 1 & -x_1 y'_1 & -y_1 y'_1 \\
 x_2 & y_2 & 1 & 0 & 0 & 0 & -x_2 x'_2 & -y_2 x'_2 \\
 0 & 0 & 0 & x_2 & y_2 & 1 & -x_2 y'_2 & -y_2 y'_2 \\
 x_3 & y_3 & 1 & 0 & 0 & 0 & -x_3 x'_3 & -y_3 x'_3 \\
 0 & 0 & 0 & x_3 & y_3 & 1 & -x_3 y'_3 & -y_3 y'_3 \\
 \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots
 \end{bmatrix}
 \begin{array}{c} \mathbf{a} \end{array}
 =
 \begin{array}{c} \mathbf{b} \end{array}
 \begin{bmatrix}
 h_{00} \\
 h_{01} \\
 h_{02} \\
 h_{10} \\
 h_{11} \\
 h_{12} \\
 h_{20} \\
 h_{21} \\
 h_{22}
 \end{bmatrix}
 =
 \begin{bmatrix}
 x'_0 \\
 y'_0 \\
 x'_1 \\
 y'_1 \\
 x'_2 \\
 y'_2 \\
 x'_3 \\
 y'_3 \\
 \vdots
 \end{bmatrix}$$

Use Linear Least Square to solve $\mathbf{M} \underline{\mathbf{a}} = \mathbf{b}$

Still works if overdetermined: minimize squared error $\| \mathbf{b} - \mathbf{M} \mathbf{a} \|^2$

$$\begin{aligned}\| \mathbf{b} - \mathbf{M} \mathbf{a} \|^2 &= (\mathbf{b} - \mathbf{M} \mathbf{a})^T (\mathbf{b} - \mathbf{M} \mathbf{a}) \\ &= \mathbf{b}^T \mathbf{b} - \mathbf{a}^T \mathbf{M}^T \mathbf{b} - \mathbf{b}^T \mathbf{M} \mathbf{a} + \mathbf{a}^T \mathbf{M}^T \mathbf{M} \mathbf{a} \\ &= \mathbf{b}^T \mathbf{b} - 2\mathbf{a}^T \mathbf{M}^T \mathbf{b} + \mathbf{a}^T \mathbf{M}^T \mathbf{M} \mathbf{a}\end{aligned}$$

This is convex and minimized when gradient = 0.

So we take the derivative wrt \mathbf{a} and set = 0.

$$-\mathbf{M}^T \mathbf{b} + (\mathbf{M}^T \mathbf{M}) \mathbf{a} = 0 \Leftrightarrow (\mathbf{M}^T \mathbf{M}) \mathbf{a} = \mathbf{M}^T \mathbf{b} \Leftrightarrow \mathbf{a} = (\mathbf{M}^T \mathbf{M})^{-1} \mathbf{M}^T \mathbf{b}$$

Not always numerically stable though, and what if $h_{22} = 0$?

Build the equation system with $||H|| = 1$

$||H|| = 1$:

$$x' = \frac{h_{00}x + h_{01}y + h_{02}}{h_{20}x + h_{21}y + h_{22}}$$

Multiplying through by denominator: $(h_{20}x + h_{21}y + h_{22})x' = h_{00}x + h_{01}y + h_{02}$

Rearrange:

$$h_{00}x + h_{01}y + h_{02} - h_{20}xx' + h_{21}yx' - h_{22}x' = 0$$

Same for y:

$$h_{00}x + h_{01}y + h_{02} - h_{20}xy' + h_{21}yy' - h_{22}y' = 0$$

Linear system with $\|H\| = 1$

unknowns

M

a = 0

$$\begin{bmatrix} x_0 & y_0 & 1 & 0 & 0 & 0 & -x_0x'_0 & -y_0x'_0 - x'_0 \\ 0 & 0 & 0 & x_0 & y_0 & 1 & -x_0y'_0 & -y_0y'_0 - y'_0 \\ x_1 & y_1 & 1 & 0 & 0 & 0 & -x_1x'_1 & -y_1x'_1 - x'_1 \\ 0 & 0 & 0 & x_1 & y_1 & 1 & -x_1y'_1 & -y_1y'_1 - y'_1 \\ x_2 & y_2 & 1 & 0 & 0 & 0 & -x_2x'_2 & -y_2x'_2 - x'_2 \\ 0 & 0 & 0 & x_2 & y_2 & 1 & -x_2y'_2 & -y_2y'_2 - y'_2 \\ x_3 & y_3 & 1 & 0 & 0 & 0 & -x_3x'_3 & -y_3x'_3 - x'_3 \\ 0 & 0 & 0 & x_3 & y_3 & 1 & -x_3y'_3 & -y_3y'_3 - y'_3 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \end{bmatrix} \begin{bmatrix} h_{00} \\ h_{01} \\ h_{02} \\ h_{10} \\ h_{11} \\ h_{12} \\ h_{20} \\ h_{21} \\ h_{22} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ \vdots \end{bmatrix}$$

Solve the system

Challenges:

- Overcomplete system
- Probably no exact solution because of noise

Solutions:

Use total least square with singular value decomposition (SVD)

[enough math here]

So: given enough matches, we get an estimate of H's parameters.

How reliable is the estimate? (Least square output)

(Example on fitting 2 parameters)

Perfect data \Rightarrow Everything is fine
but...

Is our data perfect?

How reliable is the estimate? (Least square output)

(Example on fitting 2 parameters)

Error based on squared residual

Very scared of being wrong, even
for just one point

Very bad at handling outliers in data

Even worse

(Example on fitting 2 parameters)

Multiple structures can also skew the results.

The fit procedure **implicitly assumes** there is **only one instance** of the model in the data.

Overcoming Least Square limitations

We need a robust estimation.

Approach: view estimation as a **two-stage process**:

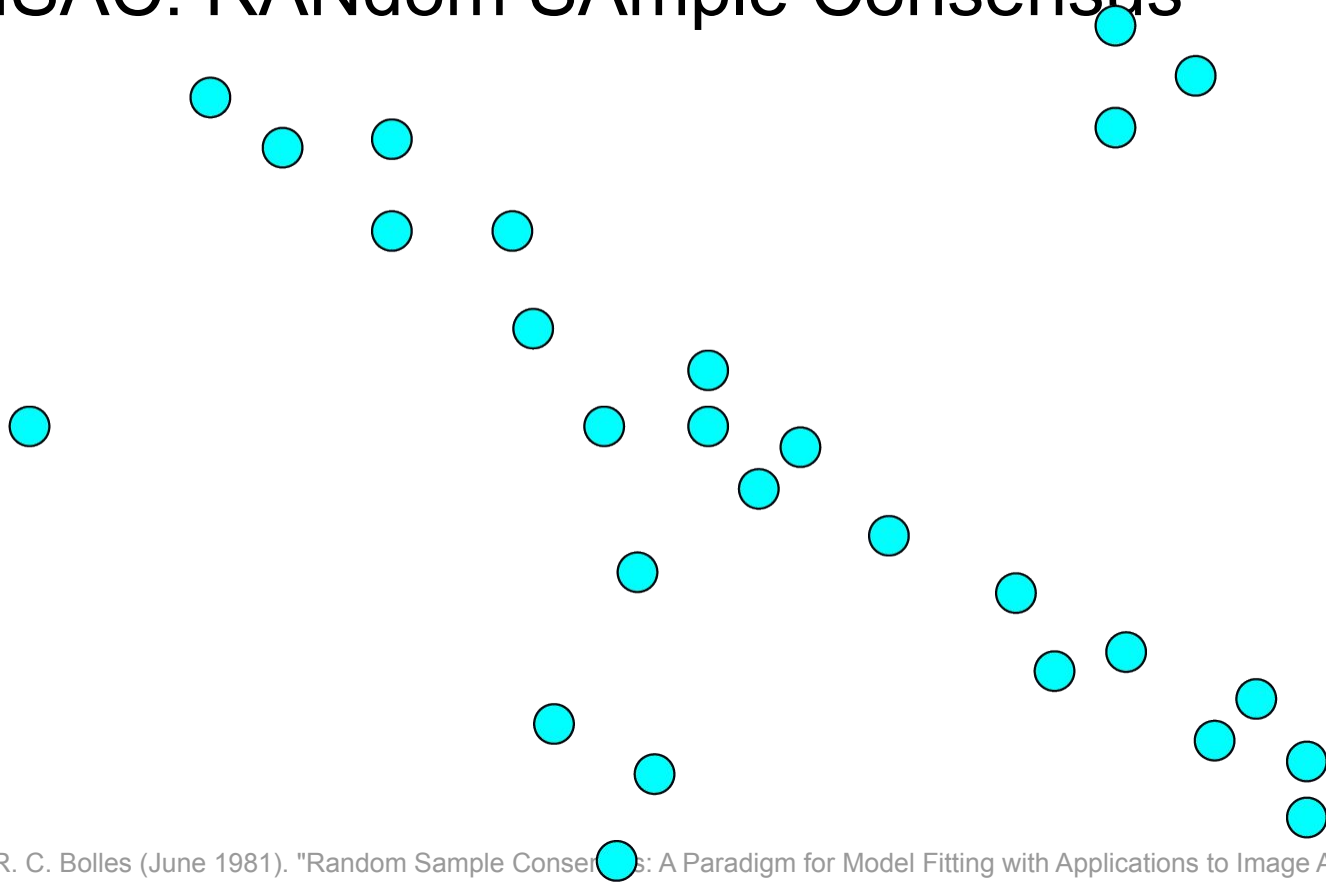

1. Classify data points as outliers or inliers
2. Fit model to inliers while ignoring outliers

Assumptions: outliers are random and will not agree

How? Try many models on subsets of the dataset and keep the best.

Several approaches: **RANSAC**, (Generalized) Hough transform, clustering...

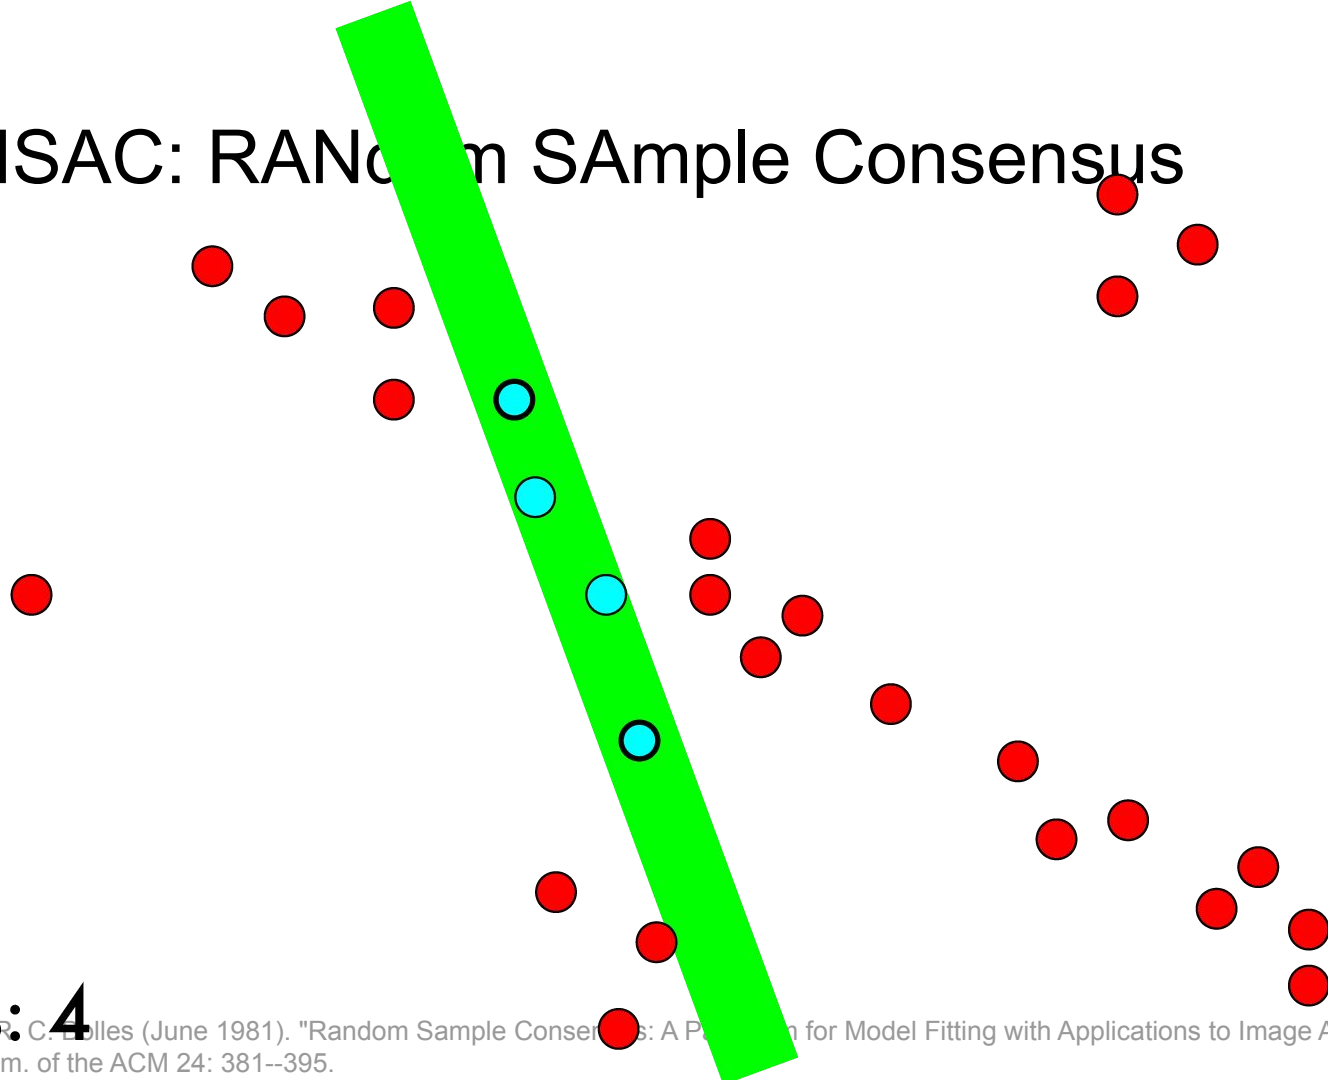

RANSAC: RANdOm SAmple Consensus

RANSAC: RANdOm SAmple Consensus

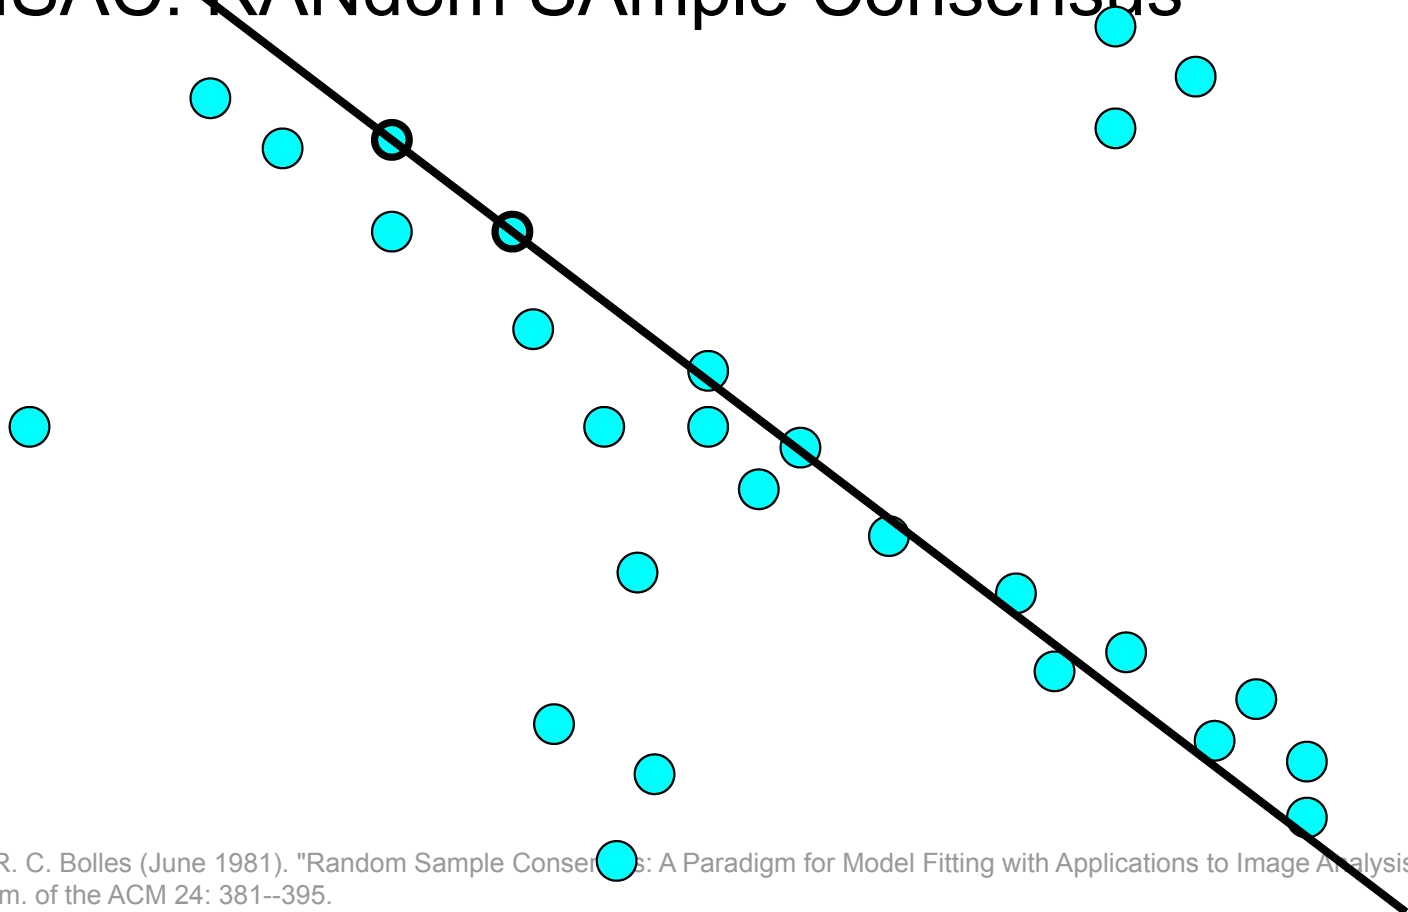

RANSAC: RANdom SAMple Consensus

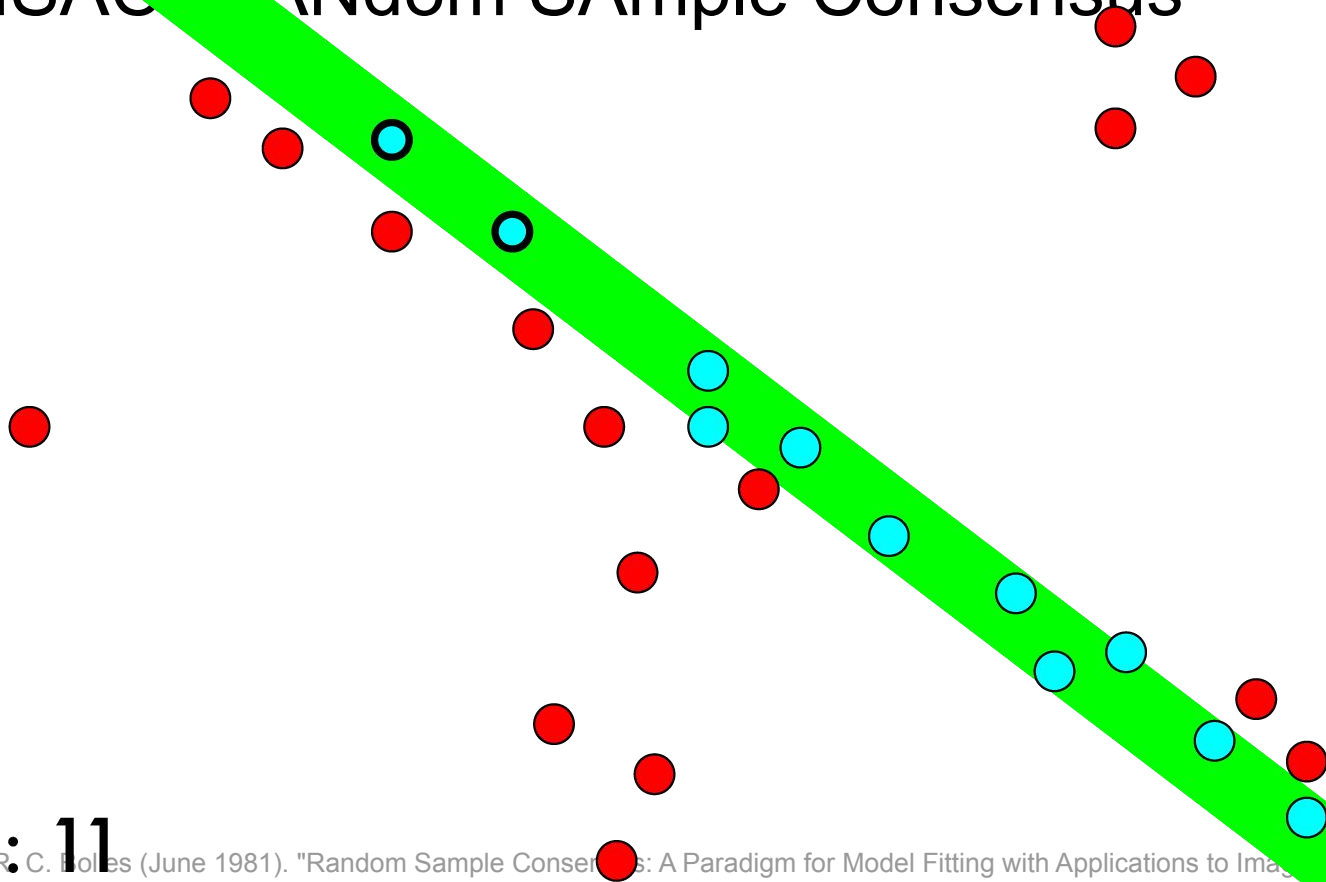

Inliers: 4

RANSAC: RANdom SAmple Consensus

RANSAC: RANdom SAmple Consensus

Inliers: 11

RANSAC: RANdOm SAmple Consensus

Inliers: 5

RANSAC: RANdom SAmple Consensus

Inliers: 7

RANSAC: RANdom SAmple Consensus

RANSAC algorithm

Parameters: **data**, **n**: num. points required to fit model, **k**: max iterations,
d: distance threshold to belong to fitted model, **m**: min. # inliers for early stop

bestmodel = None

bestfit = INF

While niter < **k**:

 sample = draw **n** random points from **data**

 Fit model to sample ← *using Least Square here*

 inliers = data within distance **d** of model ← *OpenCV uses reprojection error, ie $\|dstpoint - proj(srcpoint)\|_2 < d$*

 if inliers > **bestfit**:

 Fit model to all inliers

 bestfit = fit

 bestmodel = model

 if inliers > **m**:

 return model

return bestmodel

$$\sum_i \left(x'_i - \frac{h_{00}x_i + h_{01}y_i + h_{02}}{h_{20}x_i + h_{21}y_i + h_{22}} \right)^2 + \left(y'_i - \frac{h_{10}x_i + h_{11}y_i + h_{12}}{h_{20}x_i + h_{21}y_i + h_{22}} \right)^2$$

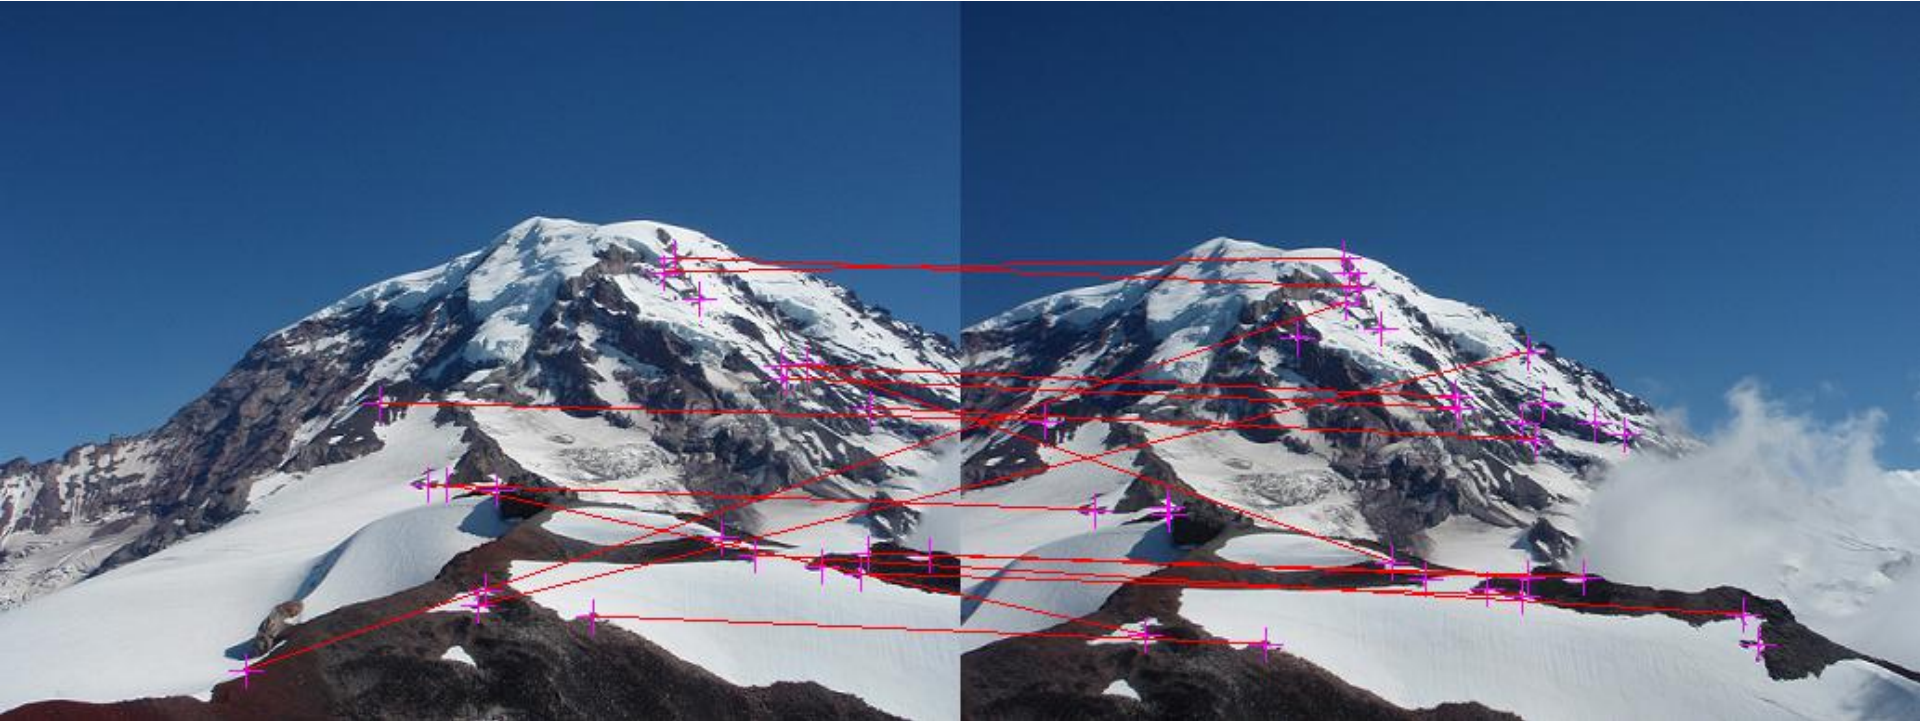

RANSAC algorithm

How to set the parameters?

Default values are usually fine in toolkits.

- **n**: num. points required to fit model
⇒ set to minimum necessary (max 8)
- **k**: max iterations
⇒ 2000 permits to be sure that at least 1 sample without outliers will be drawn with a probability $> 99\%$
- **d**: distance threshold to belong to fitted model
⇒ keep small but **may depend on problem**
- **m**: min. # inliers for early stop
⇒ should be $\gg n$, but you do not care to reach **k** anyway

RANSAC works well with extreme noise

RANSAC works well with extreme noise

Another approach: Generalized Hough Transform

Compatible with **multiple instance detection**.

Naive implementation:

1. (opt.) When matching descriptors, accept more than 1 neighbor
Recommended: use a background model to set a radius threshold
2. Estimate **all/multiple possible homographies**,
keeping track of the support points for each (= generate solution candidates)
3. Run a **clustering** (or bin counting) algorithm in the parameter space of the homography to identify the best candidates (= prune solutions)
